

# Conceptual Model of Ammonium Utilization at the Base of the Delta Food Web

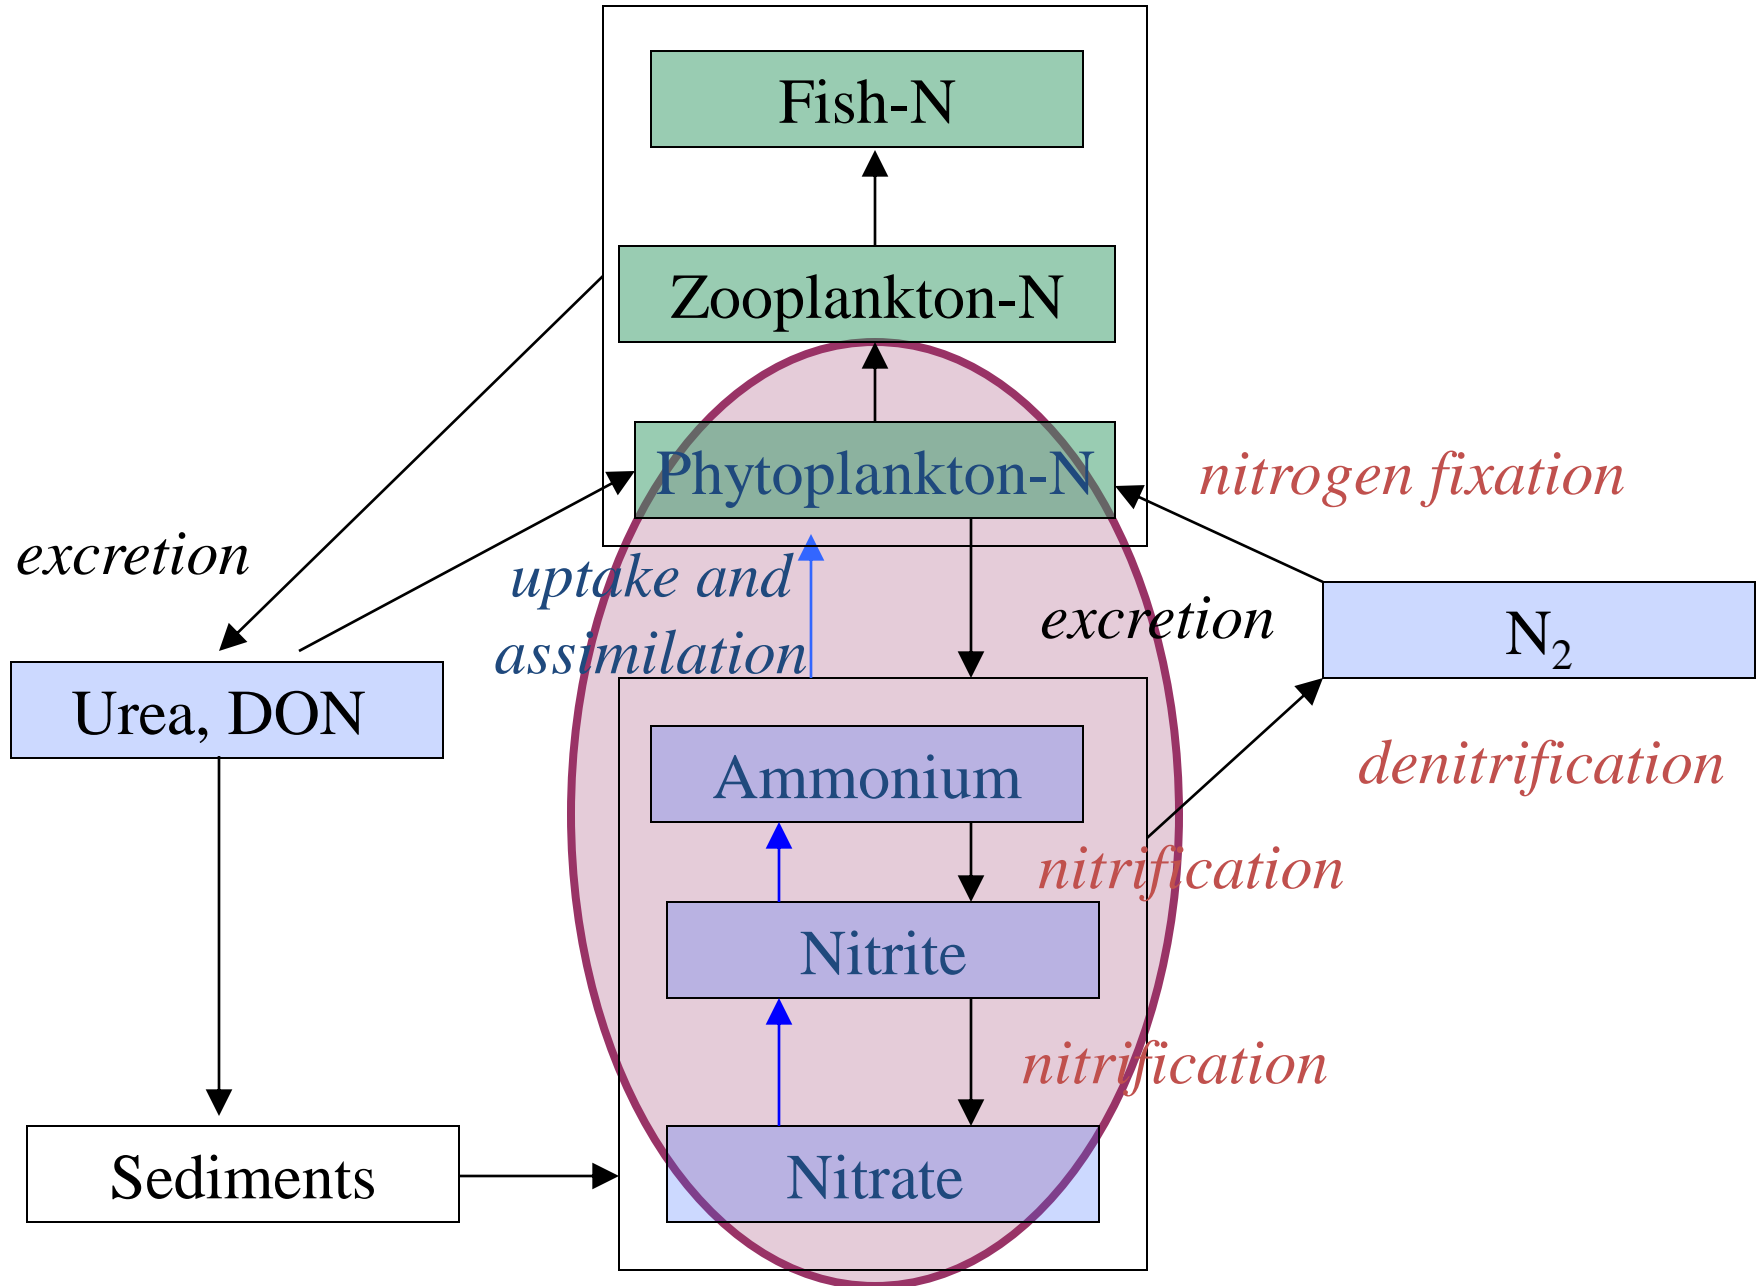

Dick Dugdale, Romberg Tiburon Center, SFSU

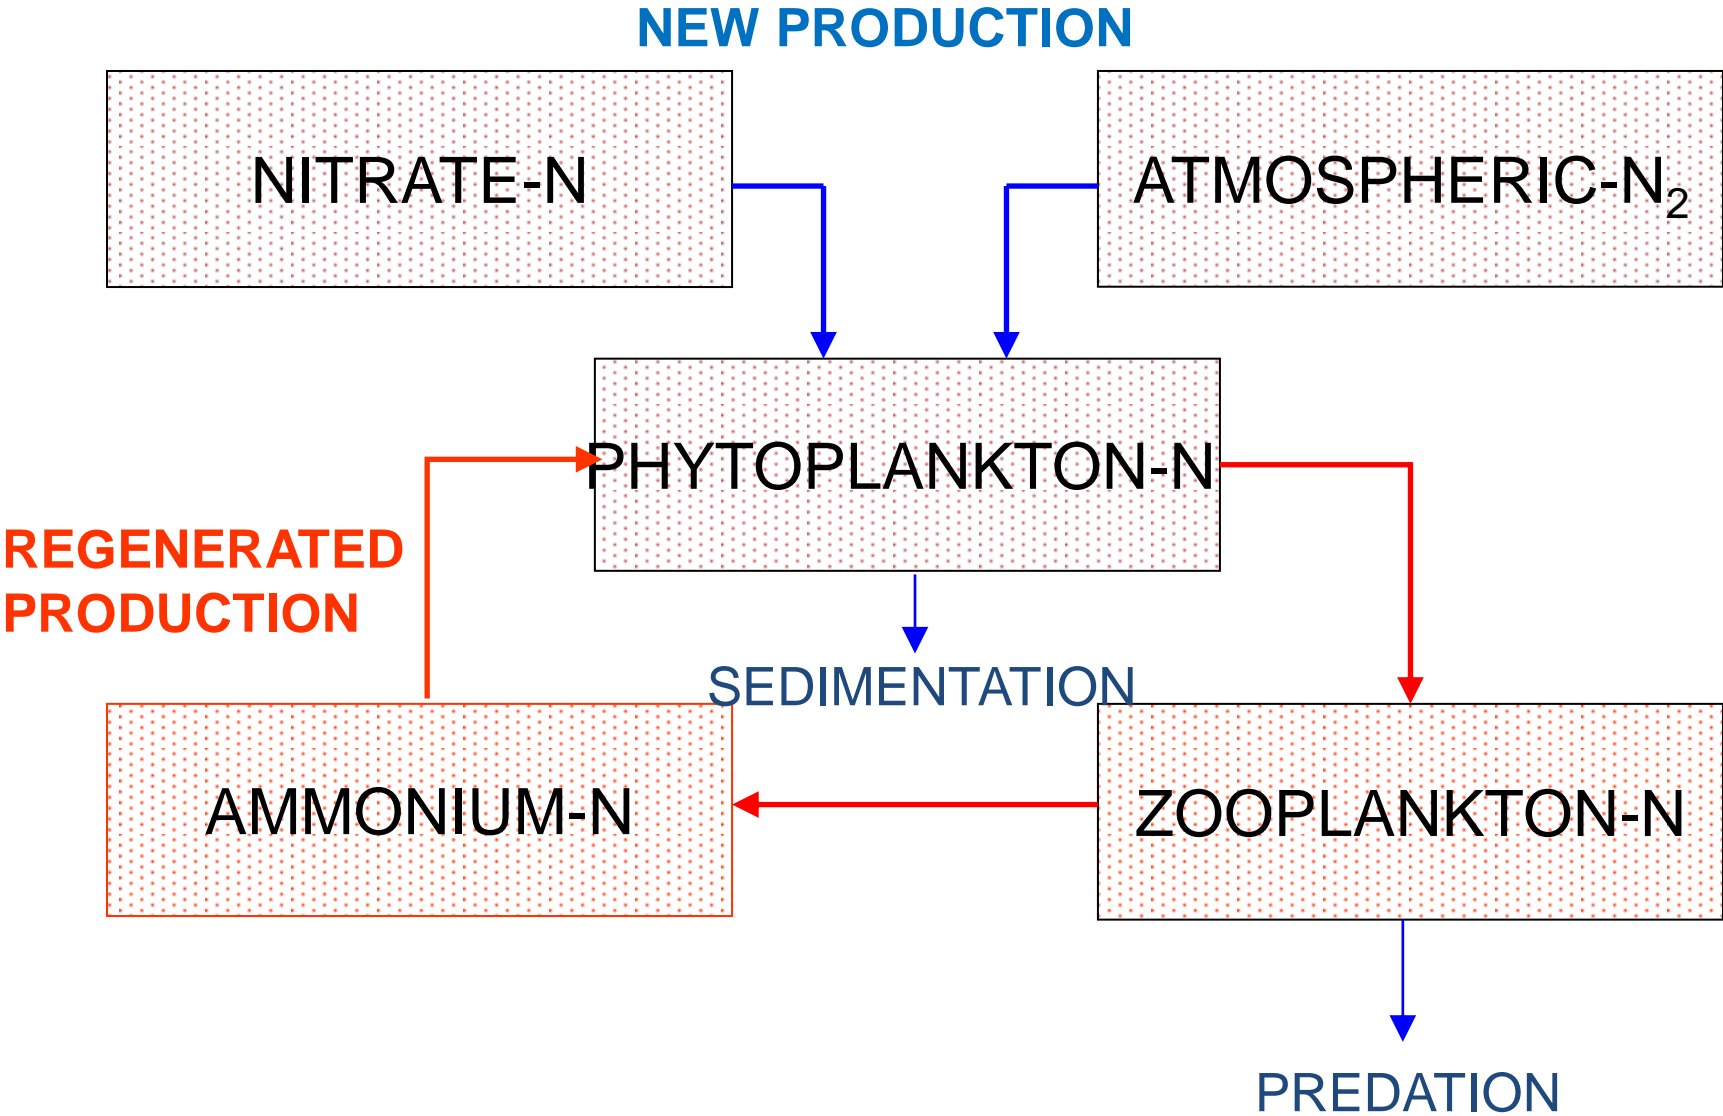

# Outline

1. Background: nitrogen cycle in the ocean
2. Background data from San Francisco Bay
3. Physiological and experimental basis for effect of ammonium on nitrate uptake by phytoplankton
4. River Transects
5. Suisun Bay spring bloom studies
6. Suisun Bay conceptual model
7. Suisun Bay  $\text{NH}_4/\text{NO}_3$  model
8. Nutrient stoichiometric ecosystem model
9. SMORE salmon model
10. COSiNE model

# Aquatic Nitrogen Cycle

# New and Regenerated Production

# Use of tracers: can track new and regenerated production with N15 labeled nitrate and ammonium measured with mass spectrometry

sample  
water

Incubate water sample containing phytoplankton with  $^{15}\text{N}$  labeled nitrate or ammonium, or  $^{13}\text{C}$  bicarbonate (C fixation)

Filter out the  
phytoplankton

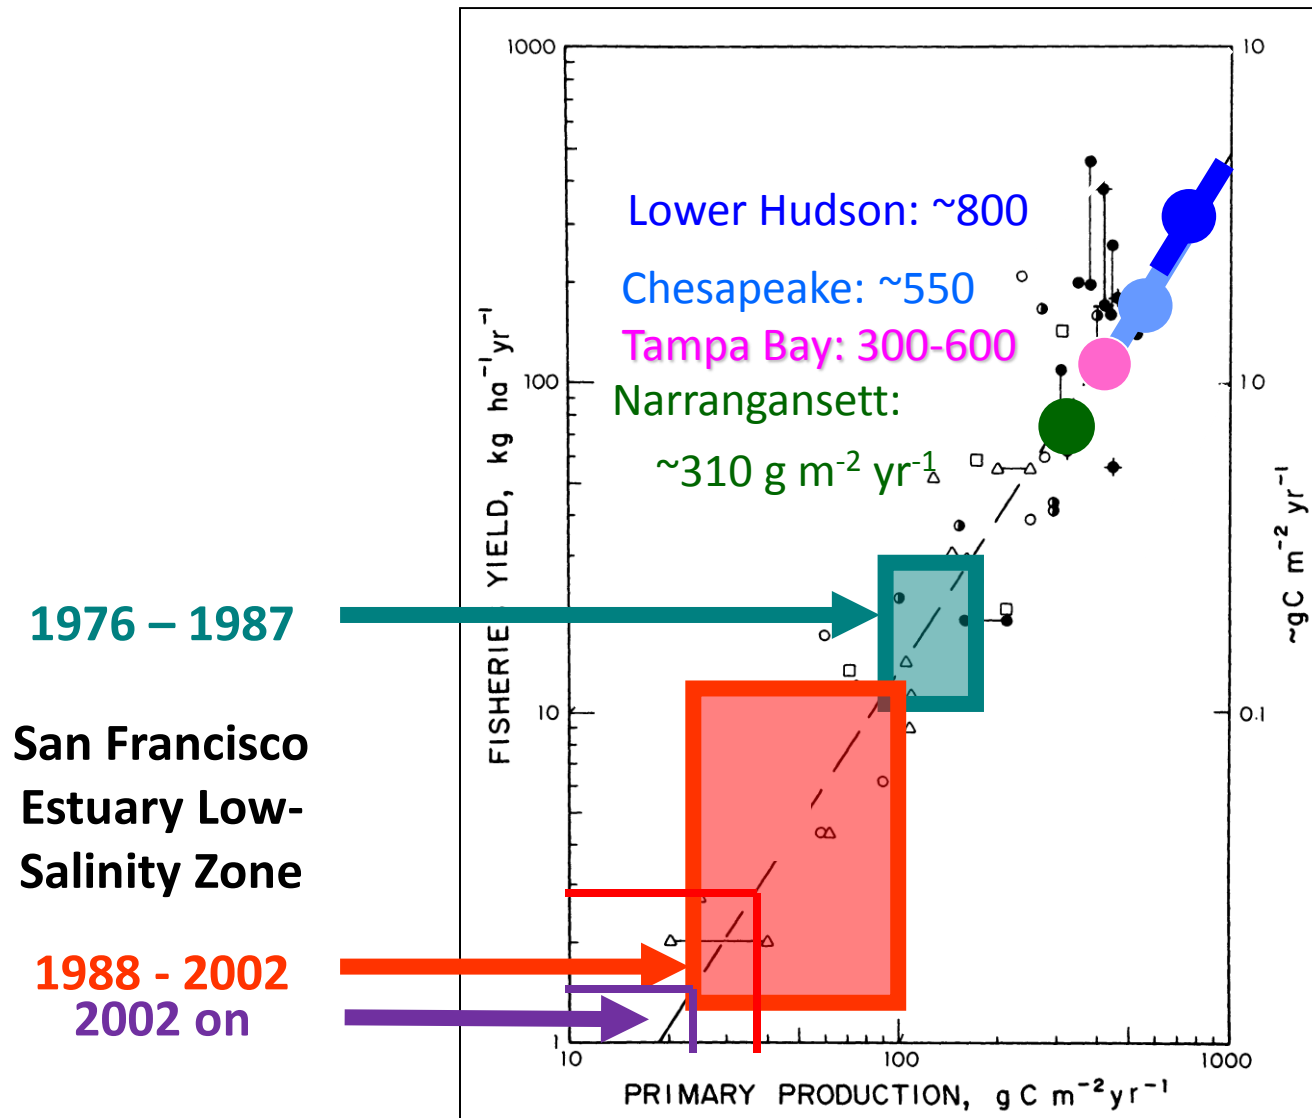

# San Francisco Estuary

The conventional wisdom for nutrients and primary productivity by phytoplankton in the San Francisco estuary is that:

- Nutrients don't matter as light is limiting, and nutrients are always in excess
- The composition of the DIN pool is unimportant since nitrate and ammonium can be used equally-worldwide
- *Corbula amurensis* (Asian clam) invasion was responsible for the collapse of the primary productivity in Suisun Bay in 1987

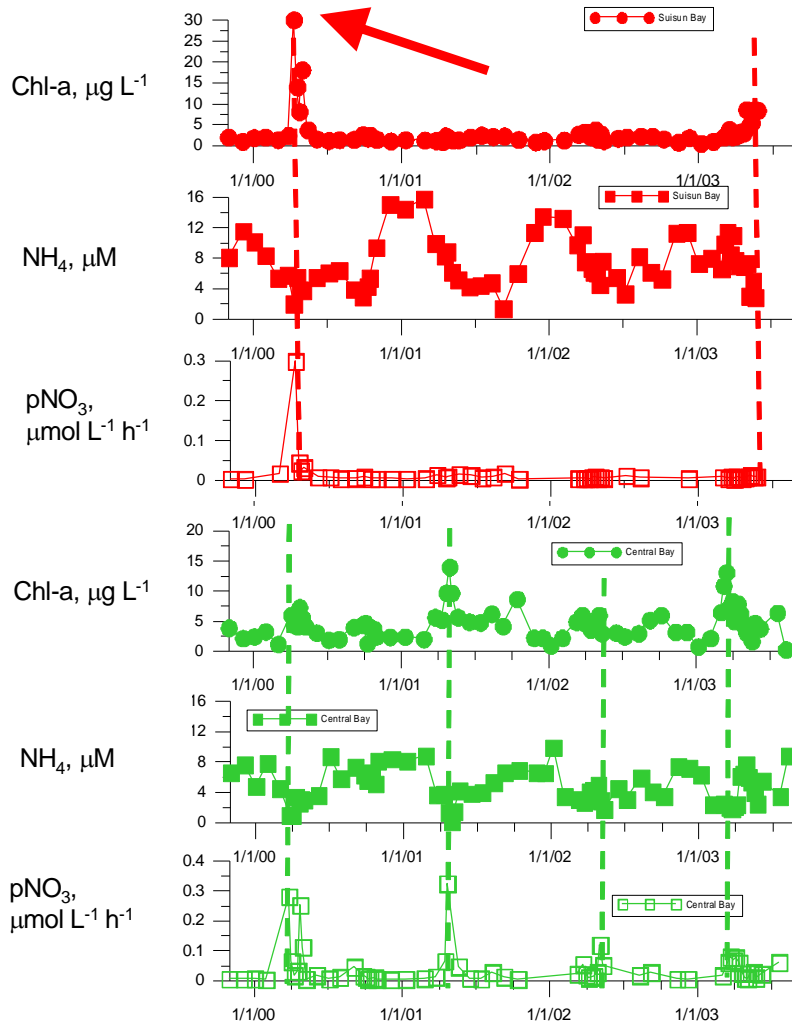

# Fishery yield directly related to primary production

## Primary production is the foundation of a healthy estuary

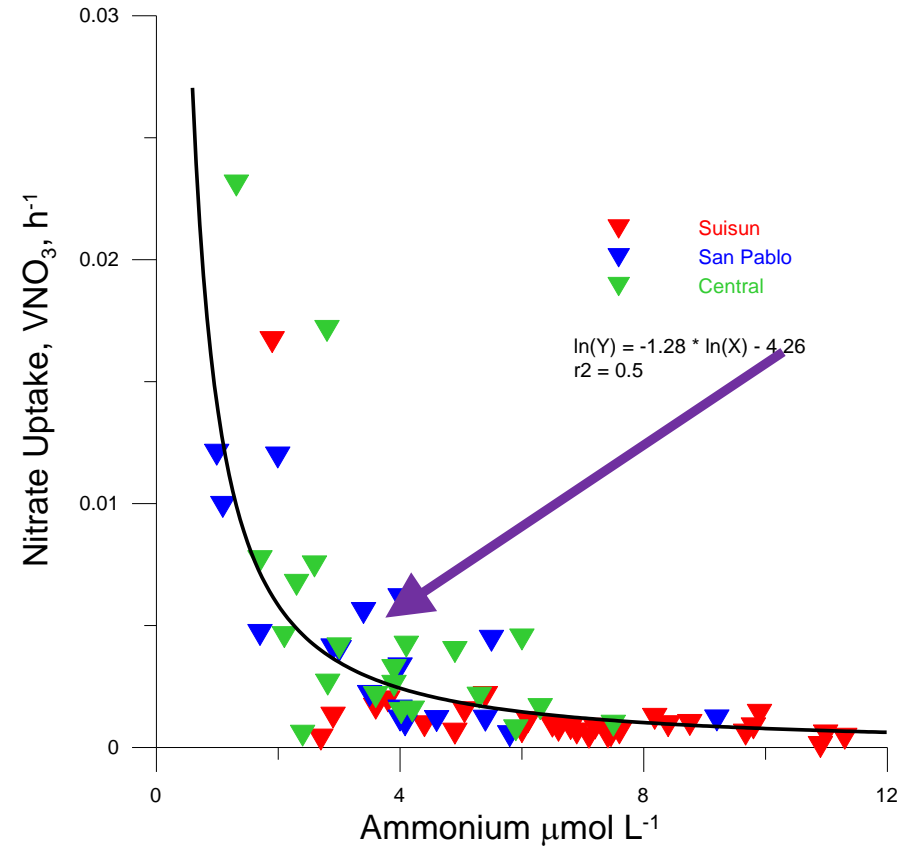

Adapted from Nixon 1988 by Cloern, Parker and others

# We observed in **Suisun** in 2000, that spring blooms happen when $\text{NH}_4$ is low

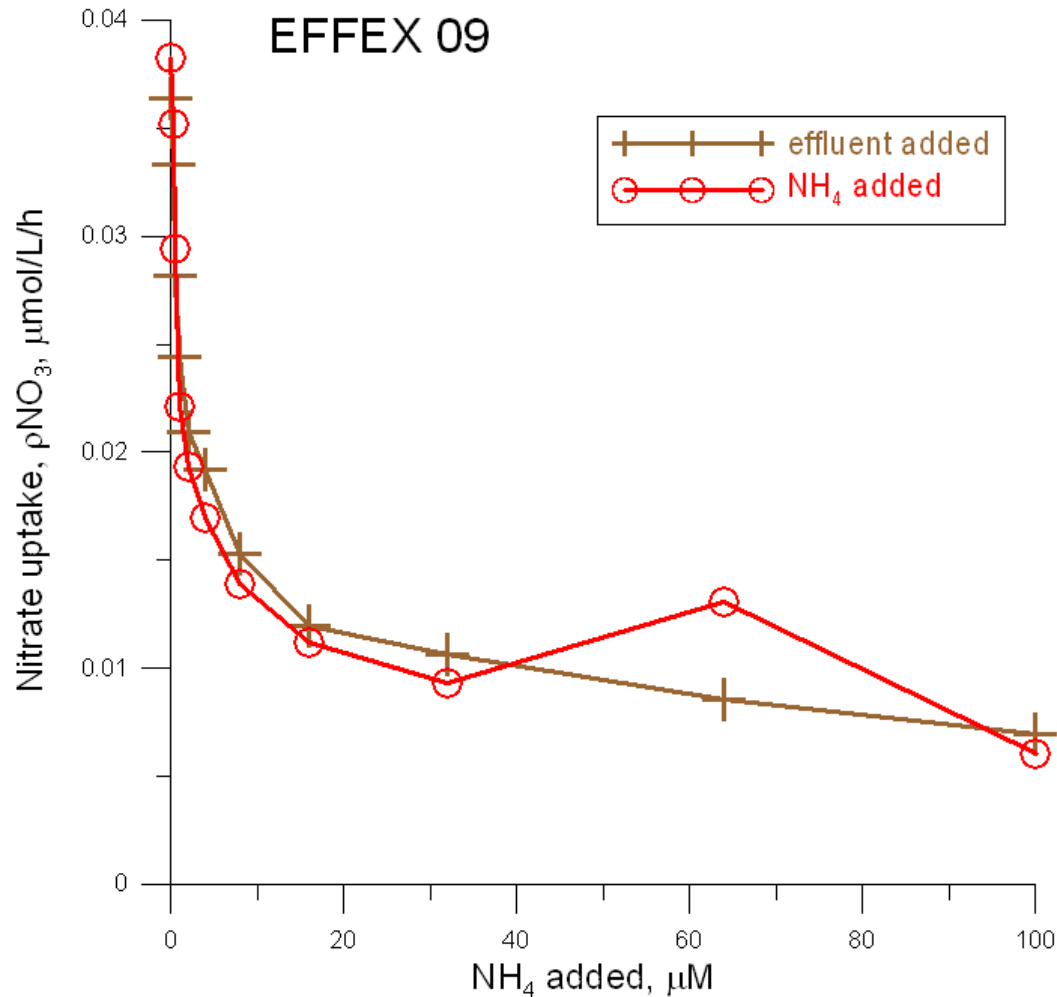

Chl accumulation (dotted line) with low  $\text{NH}_4$   
Phytoplankton need to access  $\text{NO}_3$ .

Nitrate uptake increases, once  $\text{NH}_4$  is below an inhibitory concentration

# The same relationship occurs with dilutions of effluent or $\text{NH}_4\text{Cl}$

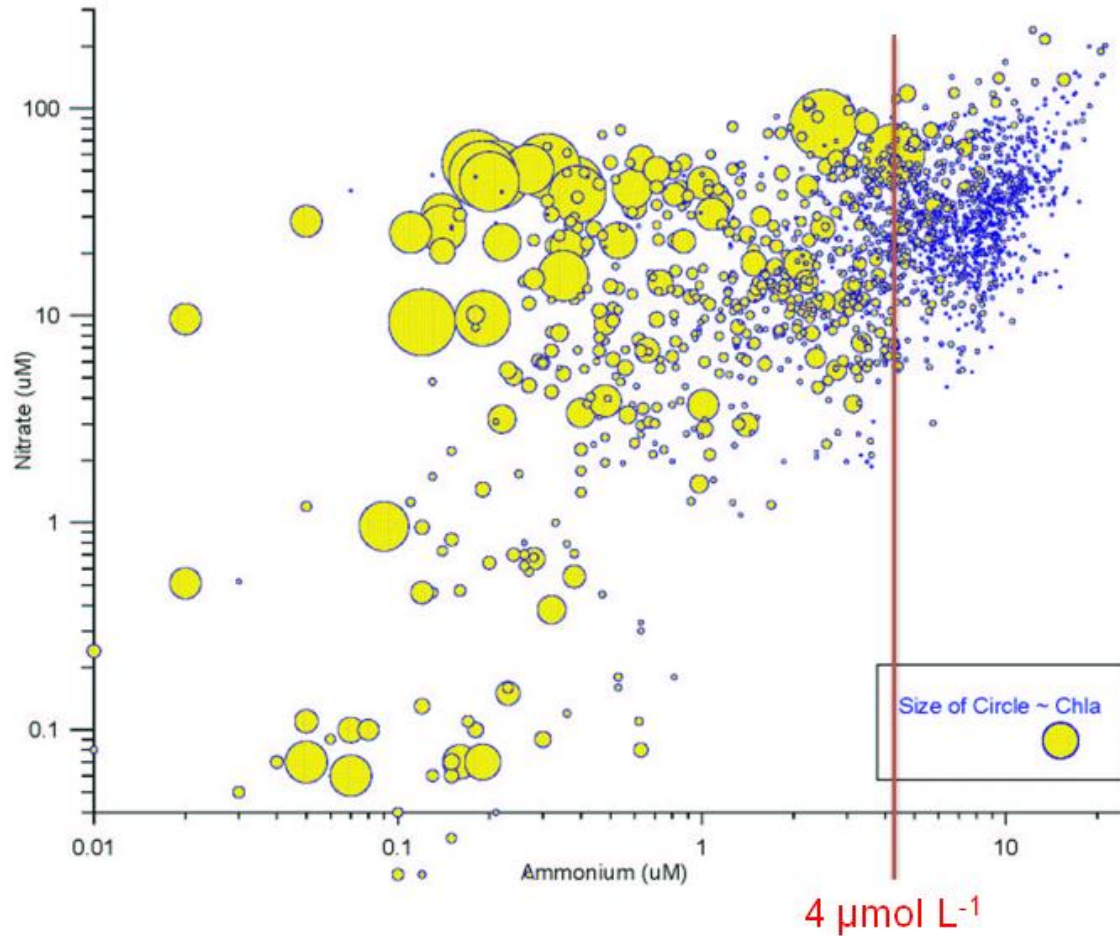

nitrate uptake decreases with high  $\text{NH}_4$  whether  $\text{NH}_4$  is in effluent or alone

# High $\text{NH}_4$ can result in decreased $\text{NH}_4$ uptake

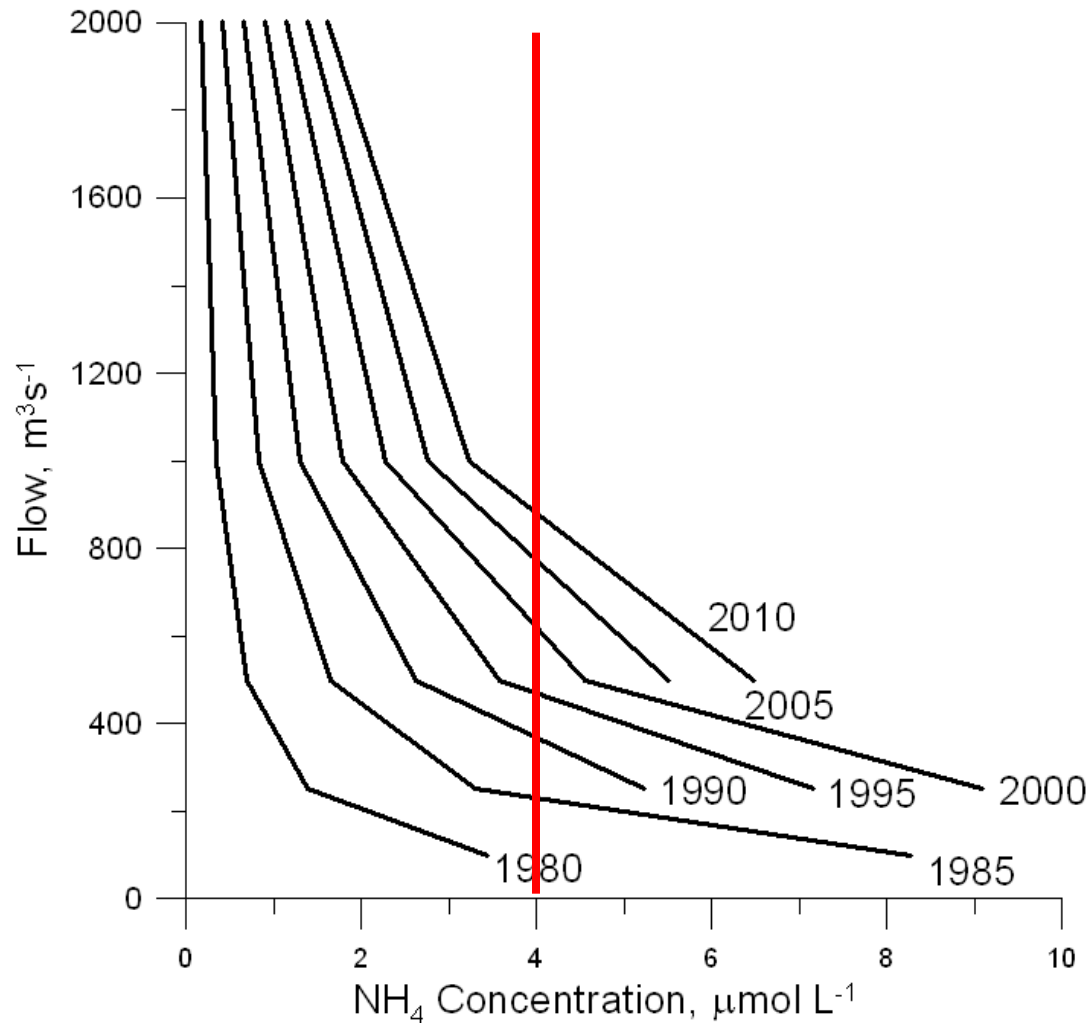

# Cloern Data for SFE – more chlorophyll (bigger circles) with less ammonium ( $\text{NH}_4$ )

# Ammonium loading has increased into Sacramento River along with population

# NH<sub>4</sub> concentrations at Suisun Bay calculated from SRWWTP discharge in different years

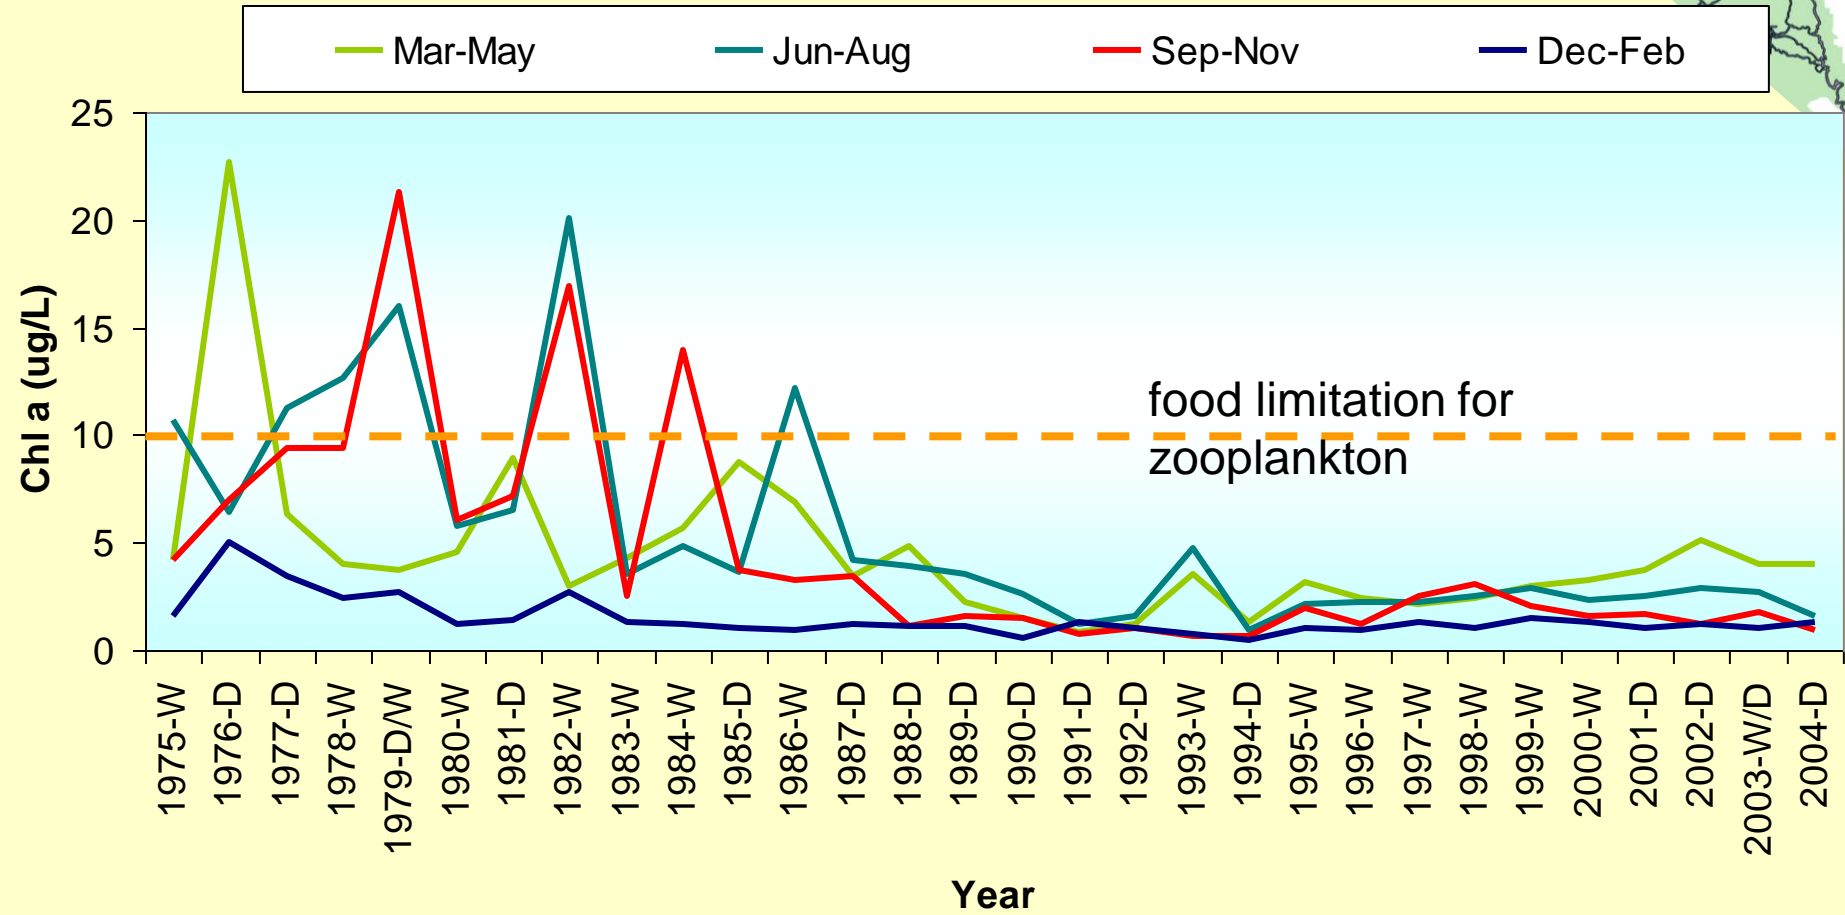

As the discharge increases, the flow needed for 4 μmol L<sup>-1</sup> (ie blooms) increases)

# In Suisun Bay, chlorophyll decreasing

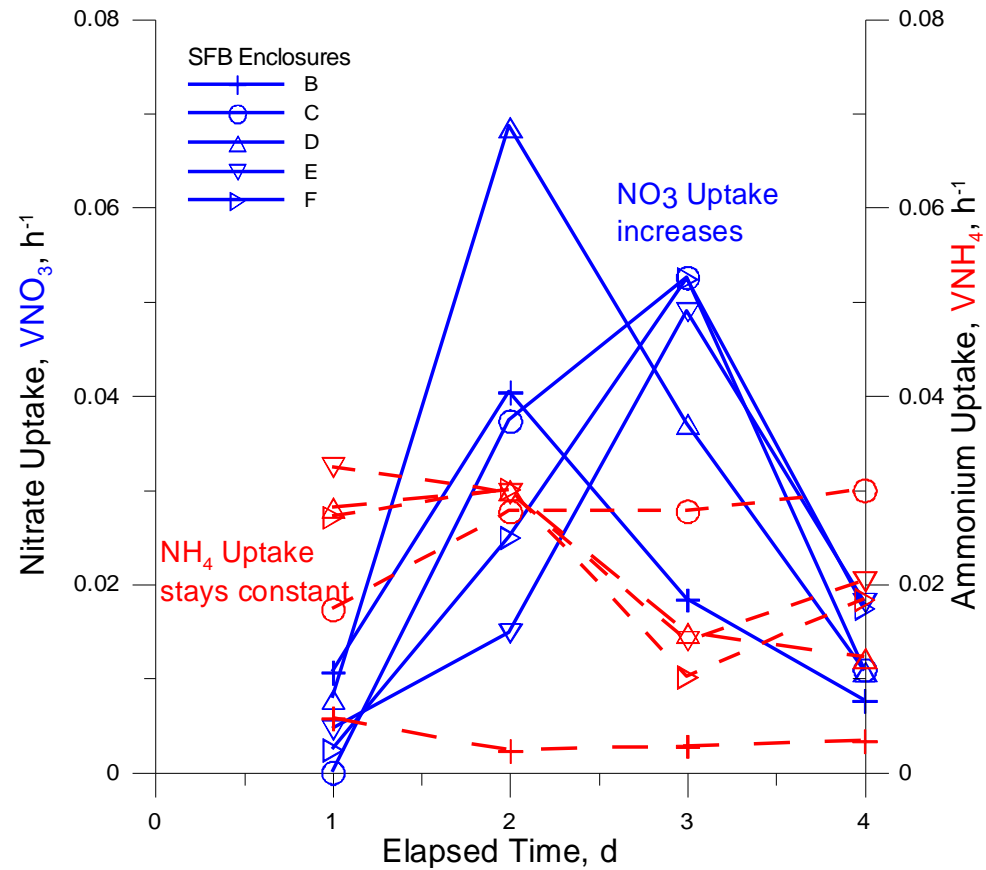

### D4 (Sac @ Pt. Sac)

# Central Bay Enclosure Experiments

Nitrate drawdown starts once NH<sub>4</sub> is reduced below inhibitory values

Nitrate uptake exceeds ammonium uptake

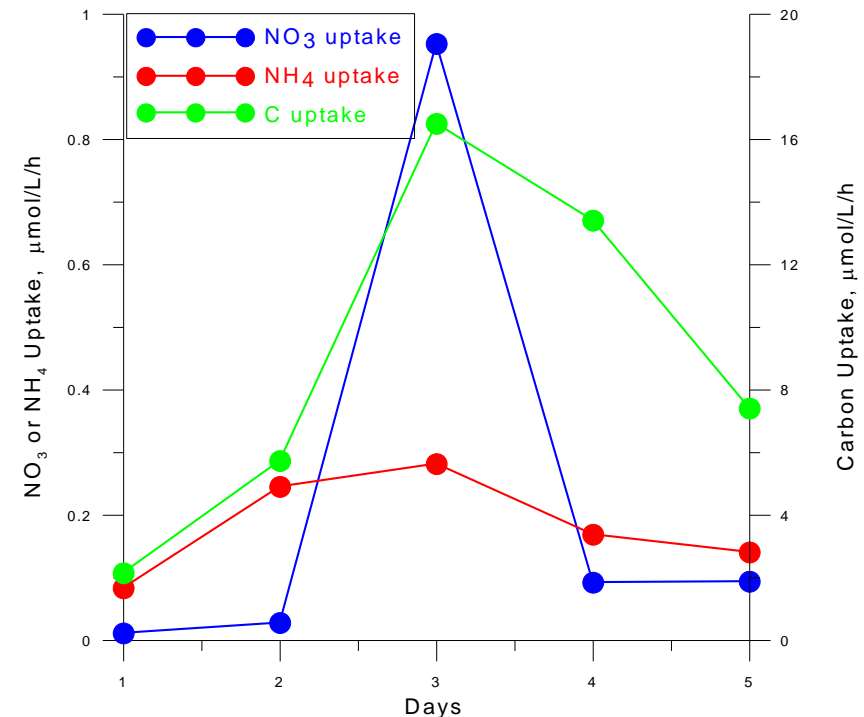

# Chlorophyll accumulation and phytoplankton productivity in Central Bay enclosures

## Nutrient drawdown and chlorophyll

$\text{NH}_4$  decreases, then when  $\text{NH}_4 \sim 4 \mu\text{M}$ ,  $\text{NO}_3$  drawdown starts on Day 2 and chlorophyll biomass increases

## Nutrient uptake and C fixation

$\text{NO}_3$  uptake is greater than  $\text{NH}_4$  uptake.  
C uptake tracks  $\text{NO}_3$  uptake.

# Carbon fixation is greater when growth is on $\text{NO}_3$ vs $\text{NH}_4$

Carbon fixation ( $\text{rho C}$ ) vs  $\text{NO}_3$  or  $\text{NH}_4$  ( $\text{rho N}$ ) uptake in enclosures in the Delaware Estuary (from Parker, 2004)

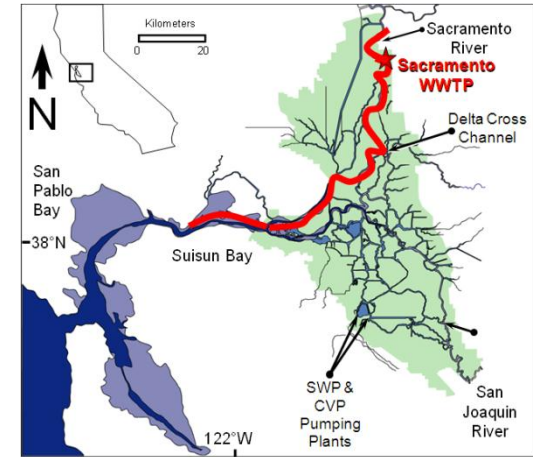

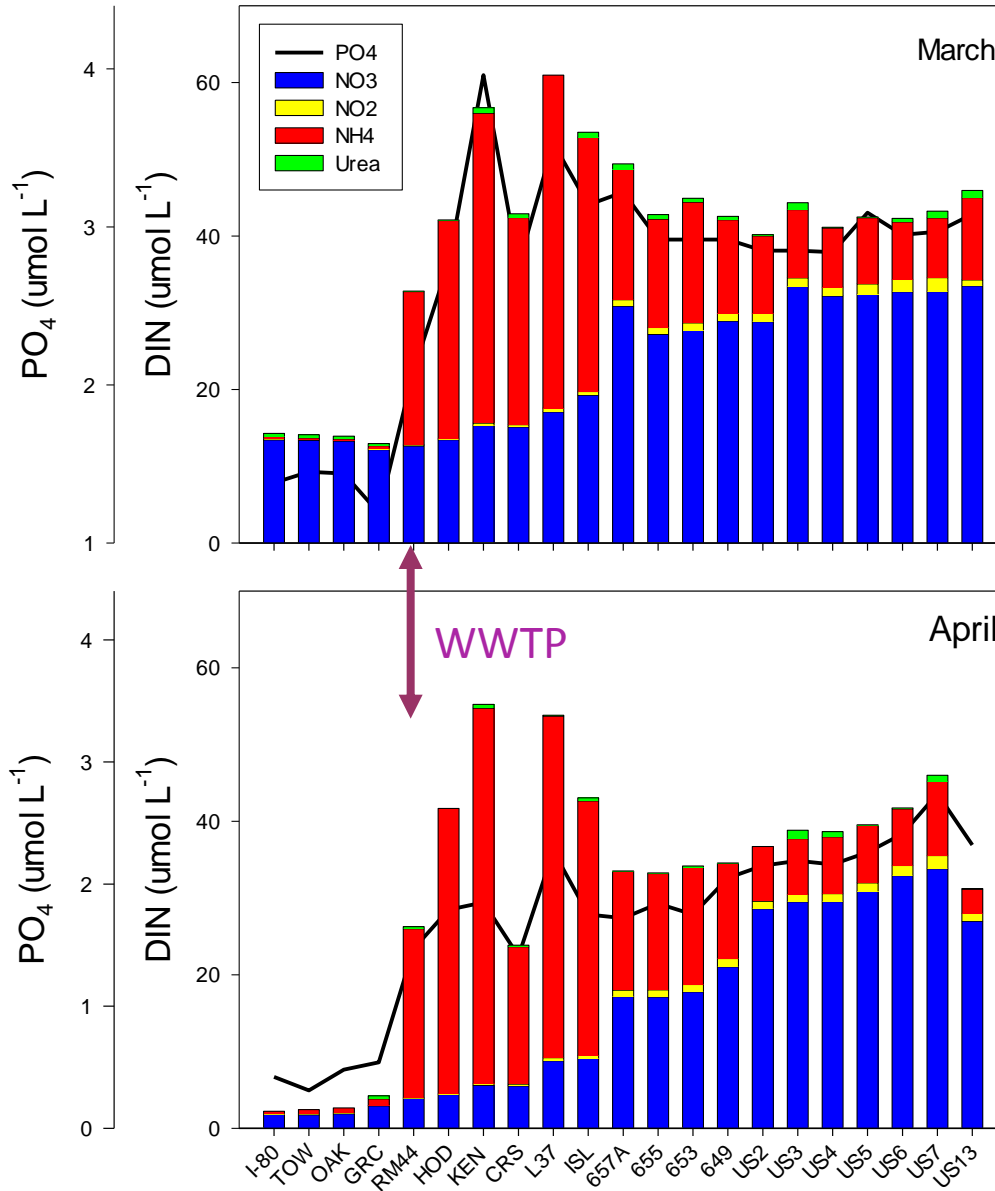

# Required sequence for bloom formation in SFE

- 1) Phytoplankton biomass buildup by uptake of  $\text{NH}_4$  (e.g. from improving irradiance, better water column stability)
- 2)  $\text{NH}_4$  concentrations decline to below  $4 \mu\text{mol L}^{-1}$
- 3) Nitrate ( $\text{NO}_3$ ) and  $\text{NH}_4$  uptake produce rapid bloom of chlorophyll

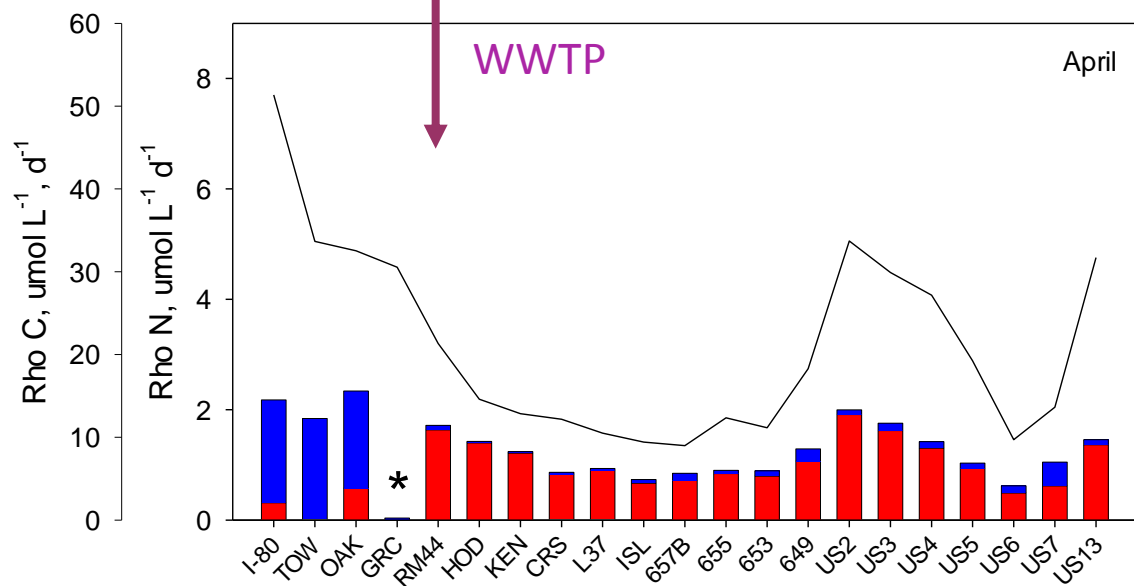

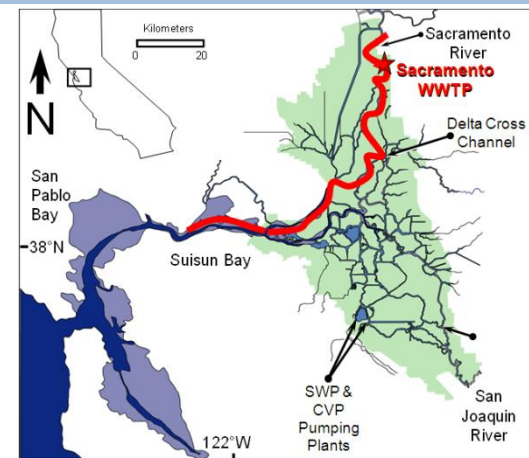

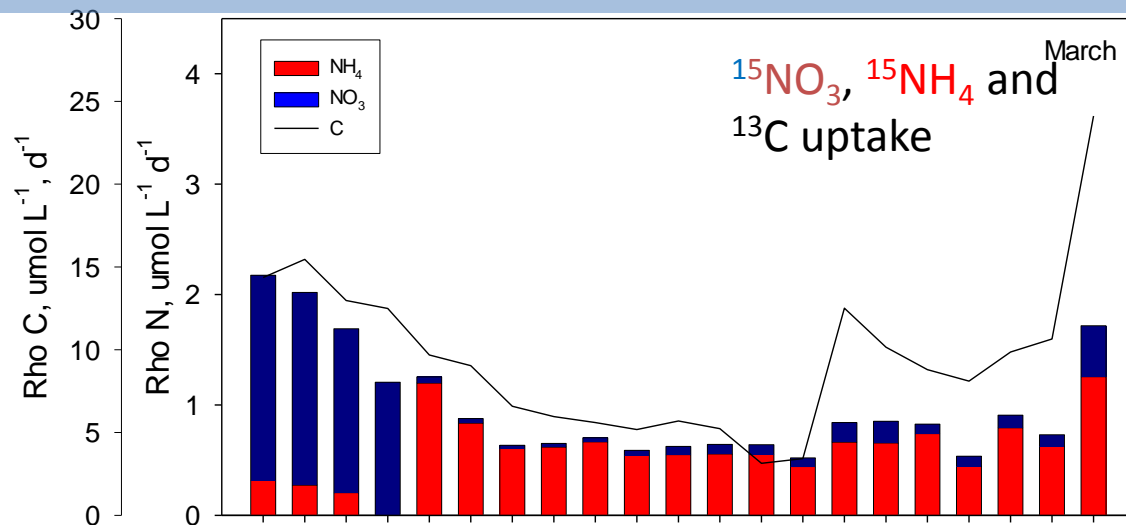

# River Transects

# Change in contribution of $\text{NO}_3$ and $\text{NH}_4$ to total DIN as go downstream

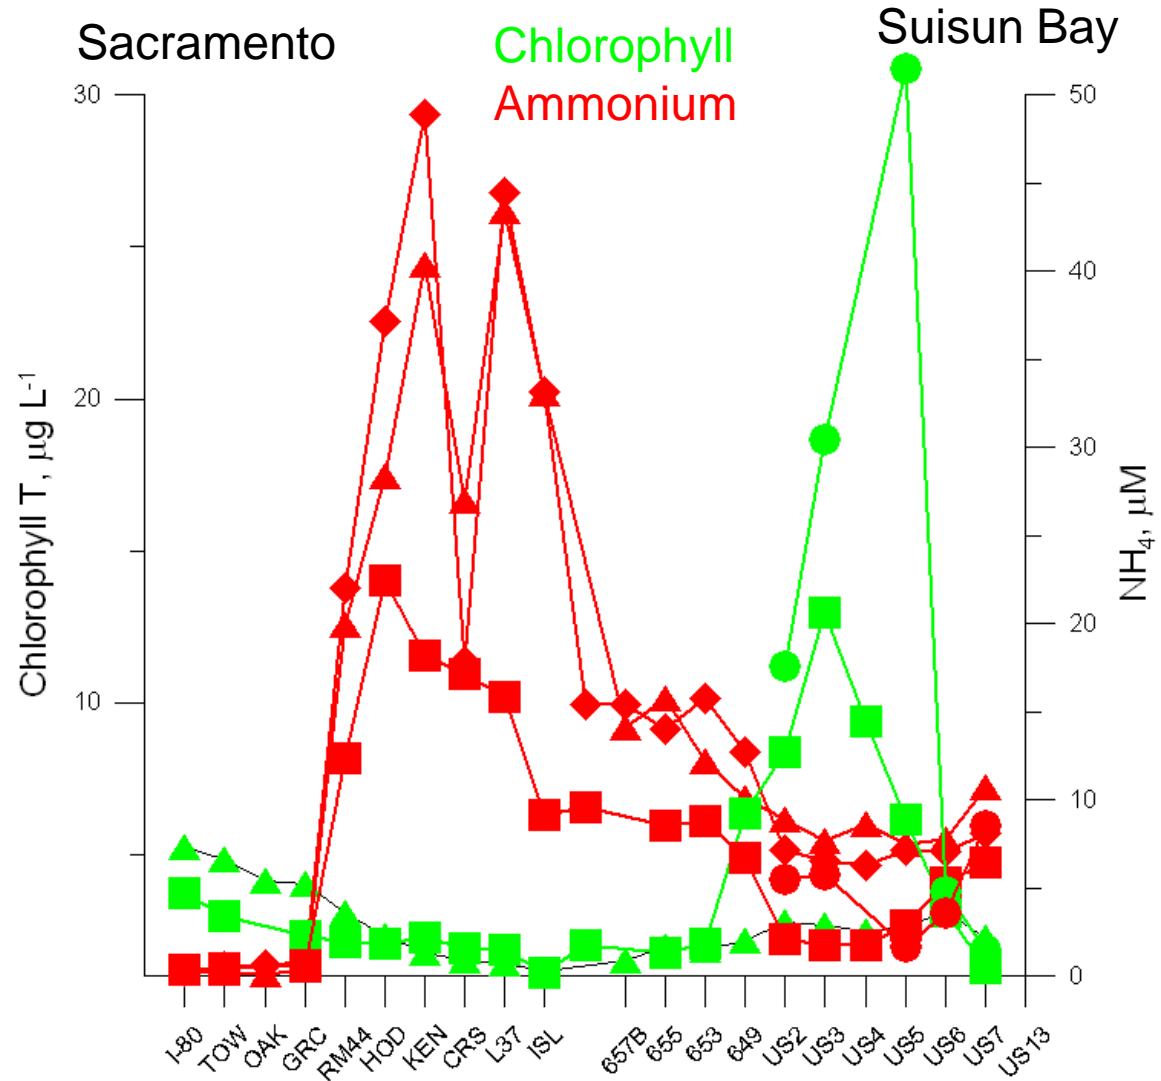

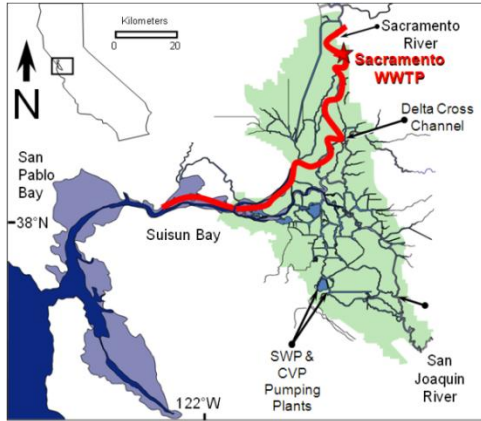

# Shift from uptake of $\text{NO}_3$ to $\text{NH}_4$ uptake system with low primary productivity (C uptake) downstream of WWTP

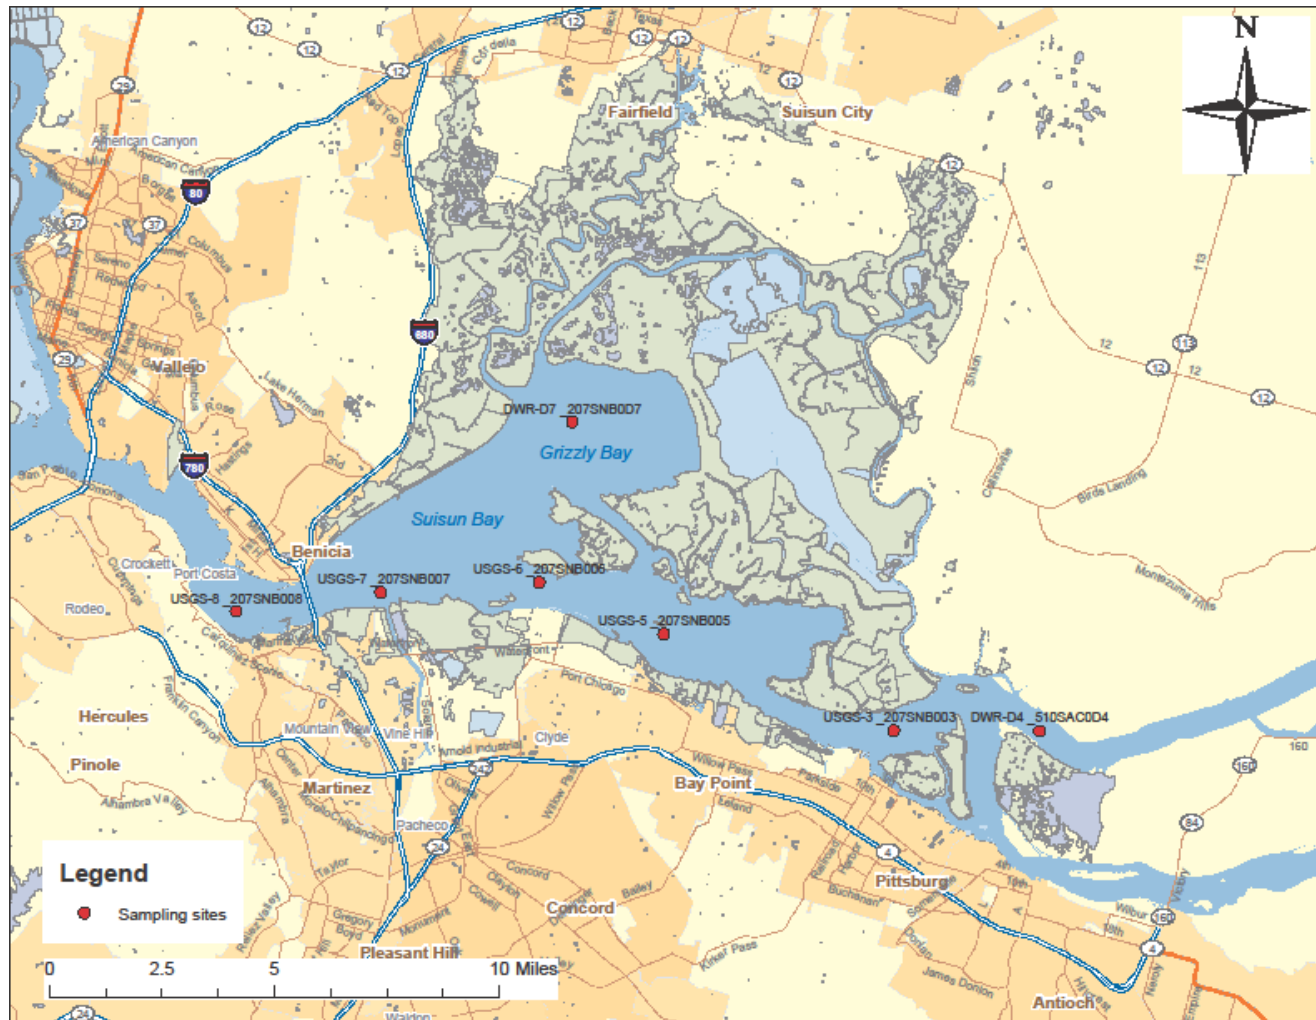

# Patterns downstream

Spring transects sampled in 2009 and 2010

# Suisun Bay spring bloom studies 2010 and 2011

*Sponsored by San Francisco Regional Water Quality Control Board, Karen Taberski*

# With high $\text{NH}_4$ concentrations, there was low chlorophyll

March 24 2010

# Phytoplankton Blooms in 2010 occurred with low $\text{NH}_4$ concentrations - as in 2000

May 24 2010

# In Suisun Bay, blooms where $\text{NH}_4 < 4 \mu\text{mol L}^{-1}$ in 2010

At the height of the bloom  $\text{NH}_4$  was  $< 4 \mu\text{mol L}^{-1}$  with high chlorophyll concentrations ( $\sim 30 \mu\text{g L}^{-1}$ ); about  $20 \mu\text{mol L}^{-1} \text{NO}_3$  was drawndown

We calculated that in 2010 there was a decline in  $\text{NH}_4$  in Sac R near the SR WTP due to increased flow and a decline in  $\text{NH}_4$  discharge

**SR WTP later explained that they had reduced  $\text{NH}_4$  discharge by 12% due to changes in treatment practices !**

# Criteria for phytoplankton to bloom in Suisun Bay (i.e. chlorophyll $> 10 \mu\text{g L}^{-1}$ ), assuming adequate light

- 1) Loading of ammonium must not exceed capacity of the phytoplankton population to take it up (or  $\text{NH}_4$  concentration will increase)
- 2) The inflowing concentration of ammonium must be close to  $4 \mu\text{mol L}^{-1}$
- 3) Flow must be less than the washout rate; i.e. basin dilution no greater than phytoplankton growth rate

# Simplified basin model for $\text{NH}_4$ criteria for blooms

$\text{NH}_4$  input from rivers

1)  $\text{NH}_4$  per day, tons N  $\text{d}^{-1}$

2) Concentration  $\mu\text{mol L}^{-1}$

Flow,  $\text{m}^3\text{d}^{-1}$

Surface area  $1.7 \times 10^8 \text{ m}^2$

Volume  $9.9 \times 10^8 \text{ m}^3$

Loading  $\text{NH}_4$  input from rivers / surface area

Phytoplankton uptake =  $V\text{NH}_4 * \text{biomass}$   
as N or chl

$\text{NH}_4$  outflow =

$\text{NH}_4$  input from rivers minus  
phytoplankton uptake

# Comparing $\text{NH}_4$ loading with phytoplankton capacity to take up $\text{NH}_4$

Range of loadings to Suisun Bay  
(from SacRegional WTP, corrected for  
nitrification)

| <i>tons N day<sup>-1</sup></i> | <i>mmolm<sup>-2</sup>d<sup>-1</sup></i> |
|--------------------------------|---|
| 5 (ca 1980)                    | 0.53                                    |
| 10                             | 1.05                                    |
| 15 (present)                   | 1.58                                    |

Range of phytoplankton uptake in  
Suisun Bay  
(from Wilkerson et al. 2007)

| <i>mmolm<sup>-2</sup>d<sup>-1</sup></i> |
|---|
| 0.49-1.2                                |

**Loading must be less than phytoplankton uptake capacity  
(or  $\text{NH}_4$  concentration will increase)**

# Comparing basin dilution with phytoplankton growth rate on $\text{NH}_4$

Basin dilution no greater than phytoplankton growth rate (or will washout)

# Threshold flows required for $4 \mu\text{mol L}^{-1} \text{NH}_4$ at Suisun with different $\text{NH}_4$ loading (5-15 tons $\text{d}^{-1}$ )

**With increasing loads the flow window gets smaller.**

**With 15 tons N loading, flows need to be between  $\sim 825$  and  $\sim 1100 \text{ m}^3 \text{s}^{-1}$**

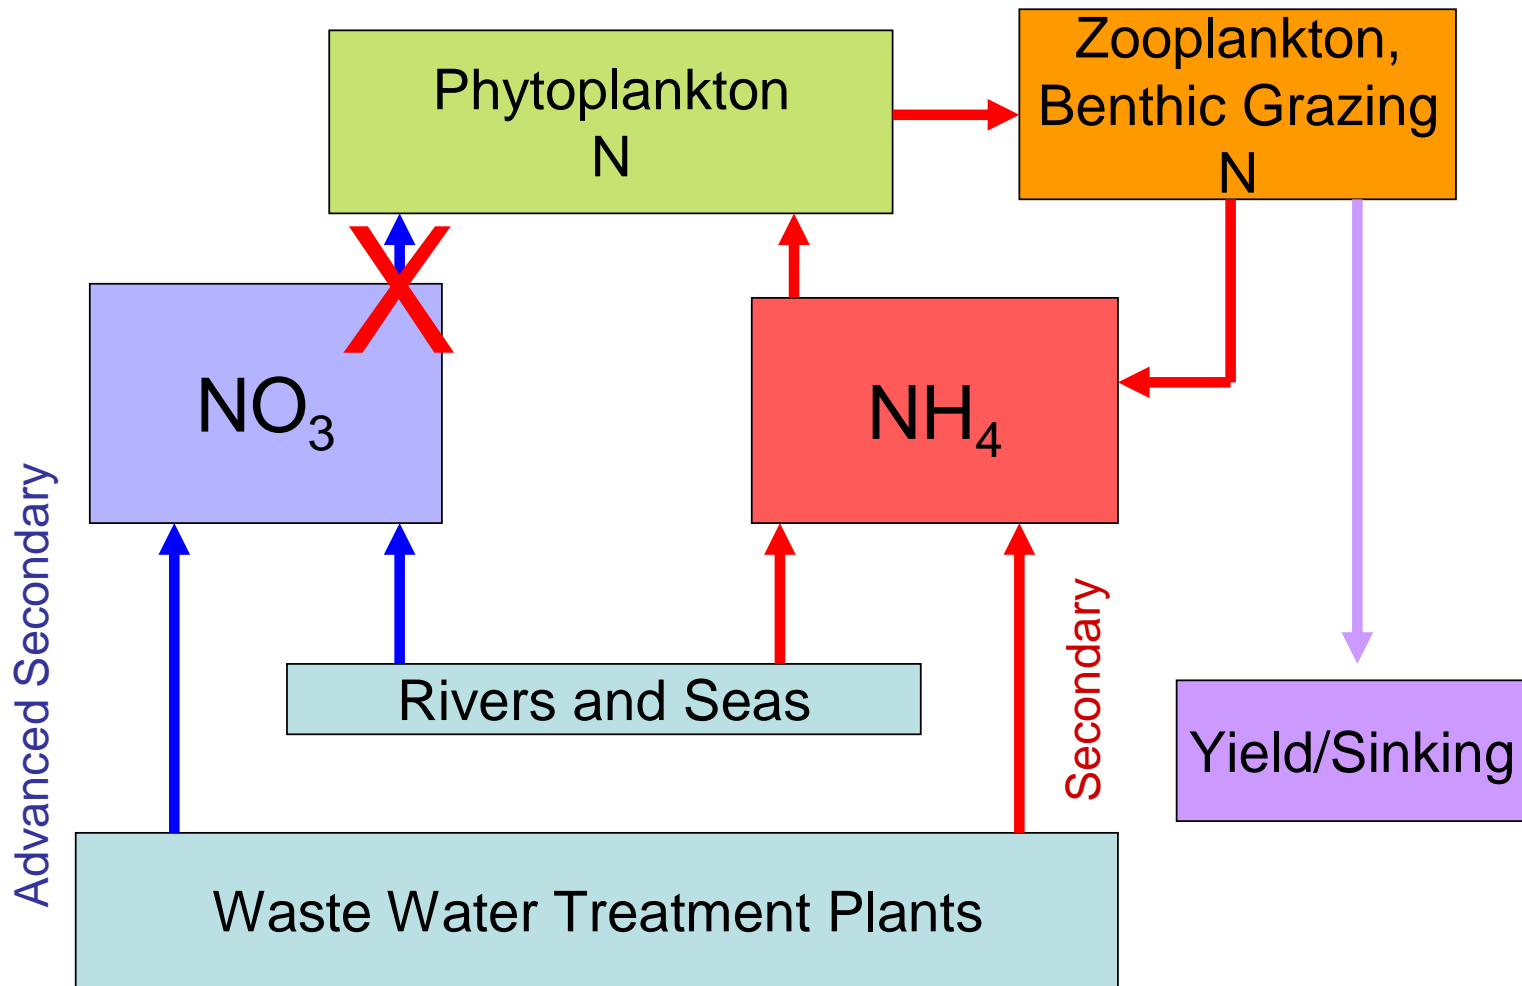

# NH<sub>4</sub> in the river at the WTP vs. river flow with curves showing relationship for different N loadings with the 4 μmol L<sup>-1</sup> concentration criterion

**Conc Crit.**  
**Flow needed to get 4 μmol at Suisun with 15 tons N loading**

**Flow during 2010 blooms was sufficient to meet the concentration criterion of 4 μmol at Suisun with ~13 tons N loading.**  
**Flow too low in 2009**

# Simplified Estuarine N Cycle

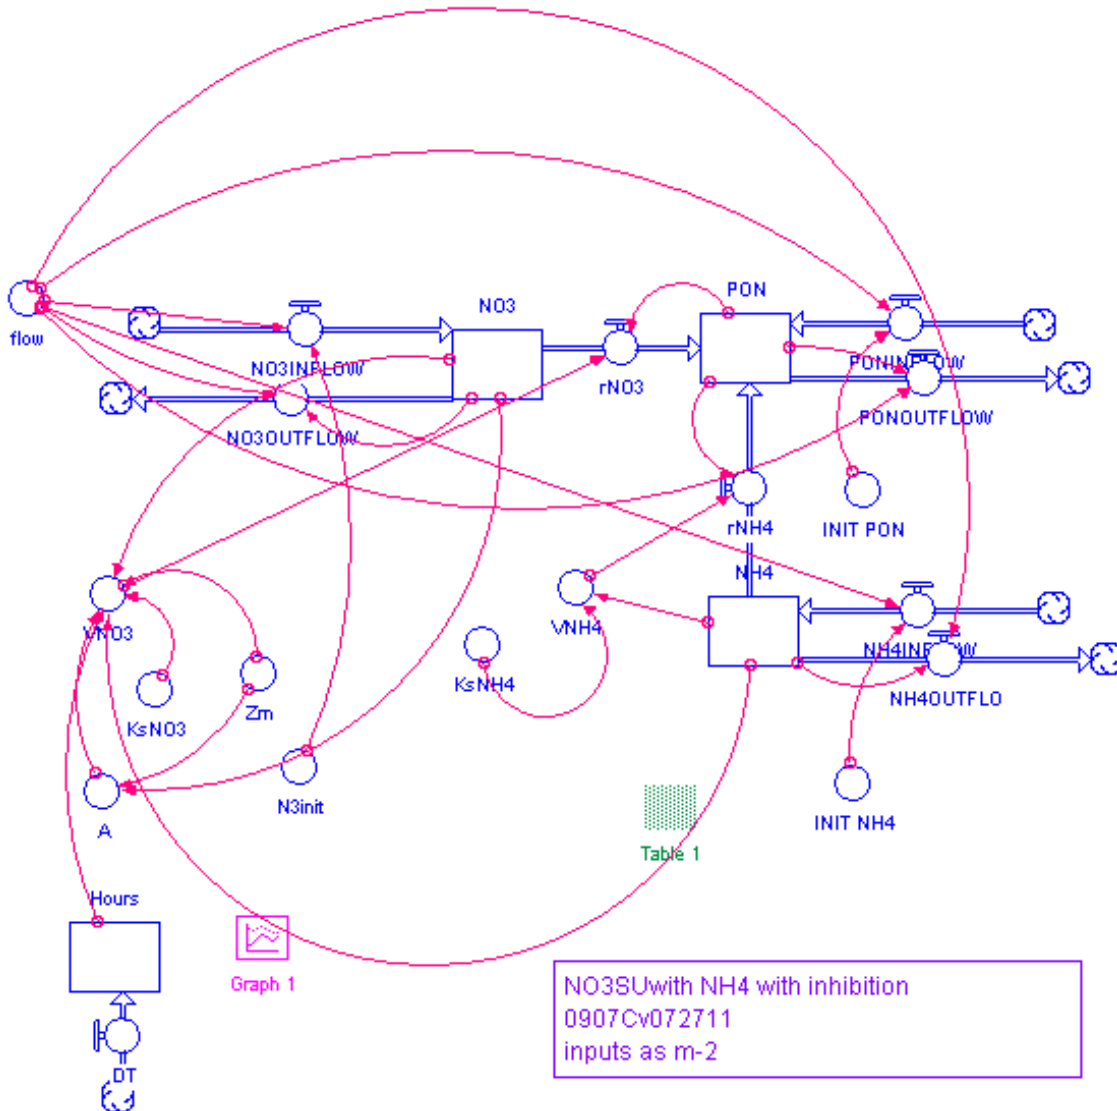

Cutting off phytoplankton access to NO<sub>3</sub> reduces potential phytoplankton biomass by 80%

# Suisun Bay $\text{NH}_4/\text{NO}_3$ model to describe $\text{NH}_4$ and $\text{NO}_3$ interactions

## Basic Equations

$\text{NH}_4$  uptake,  
Michaelis Menten  
$$V_{\text{NH}_4} = V_{\text{maxNH}_4} * \text{NH}_4 / (\text{NH}_4 + K_S)$$

$\text{NO}_3$  uptake,  
1) Acceleration kinetics  
$$V_{\text{NO}_3} = \text{NO}_3(i) + A * t$$
  
$$A = 4 \times 10^{-5} * \text{NO}_3 + 4 \times 10^{-5}$$
  
2) Inhibition by  $\text{NH}_4$ ,  
$$V_{\text{NO}_3} * \exp^{-5.59 * \text{NH}_4}$$

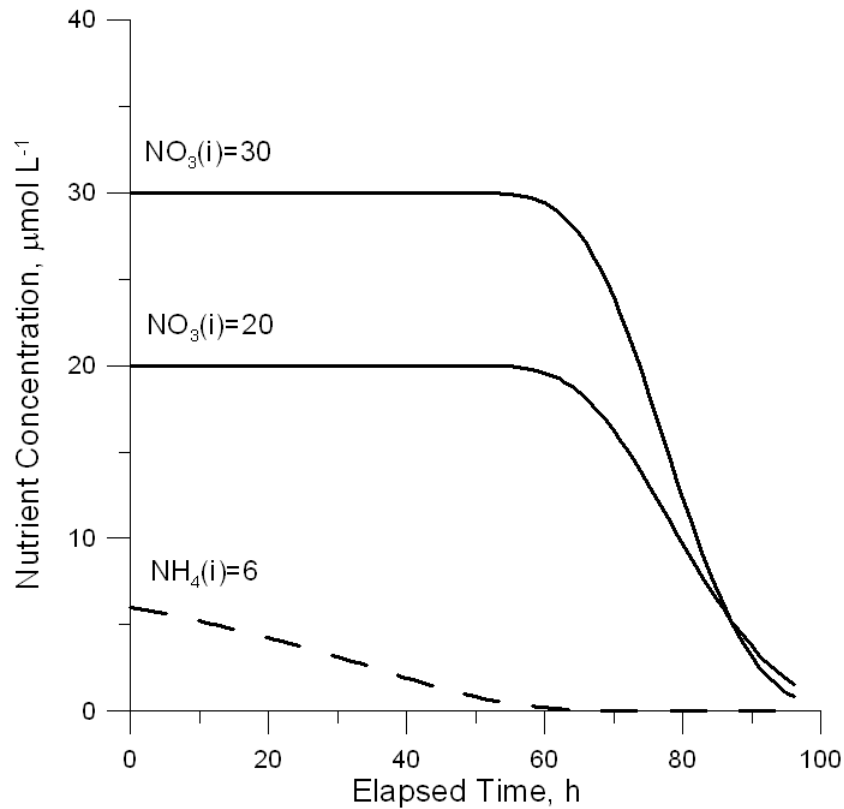

NO3SUwith NH4 with inhibition  
0907Cv072711  
inputs as m-2

Model can be run in 3 modes:

- 1) Flow set to 0, simulates enclosure experiments
- 2) Flow set to proportion of volume, simulates a fully mixed bay
- 3) Flow set to proportion of volume, inputs are as surface area integrated values, Simulates fully mixed bay with phytoplankton productivity restricted by irradiance

# 1) Flow set to 0, simulates enclosure experiments

Nitrate drawdown starts once  $\text{NH}_4$  is reduced below inhibitory values

Nitrate uptake exceeds ammonium uptake

# Central Bay Enclosures

## 2) Flow set to proportion of volume, simulates a fully mixed bay

Ammonium and Nitrate Drawdown

Growth on Ammonium and Nitrate

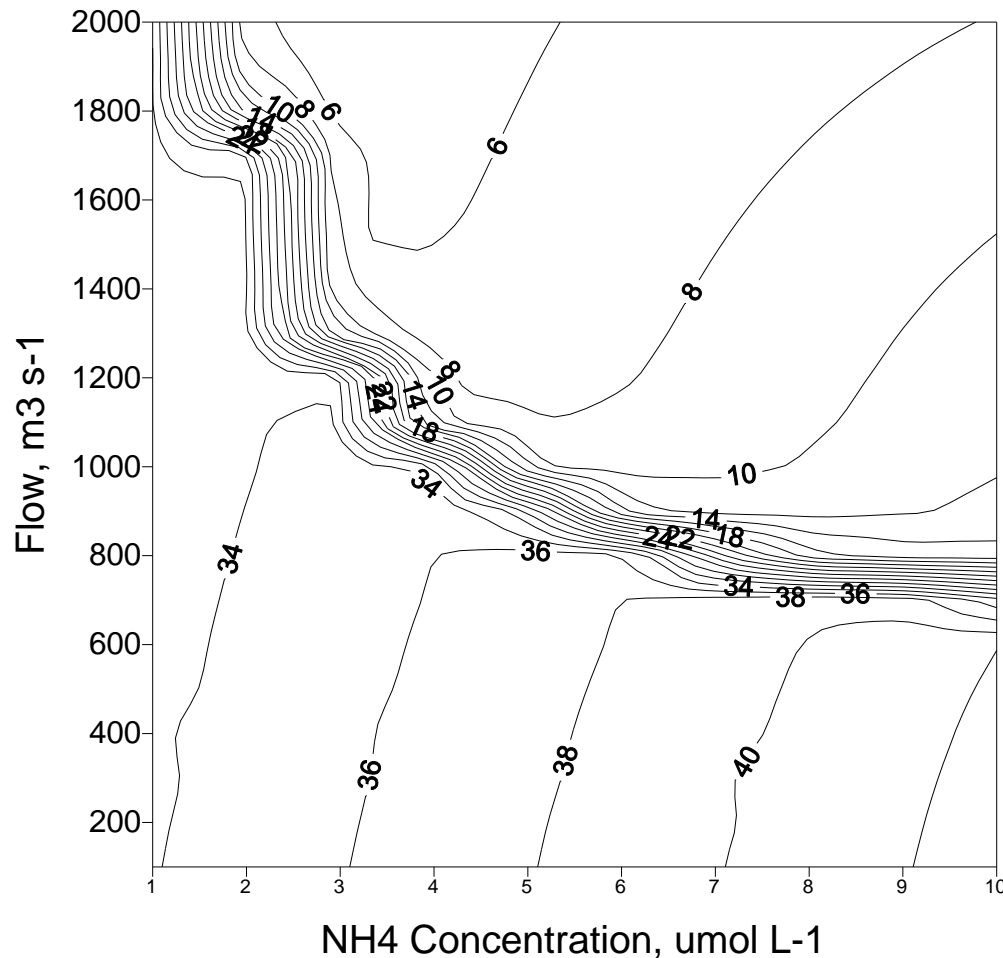

Ammonium and Nitrate Uptake

Numbers are increasing inflowing ammonium concentrations

## 2) Flow set to proportion of volume, simulates a fully mixed bay: two states of biomass accumulation

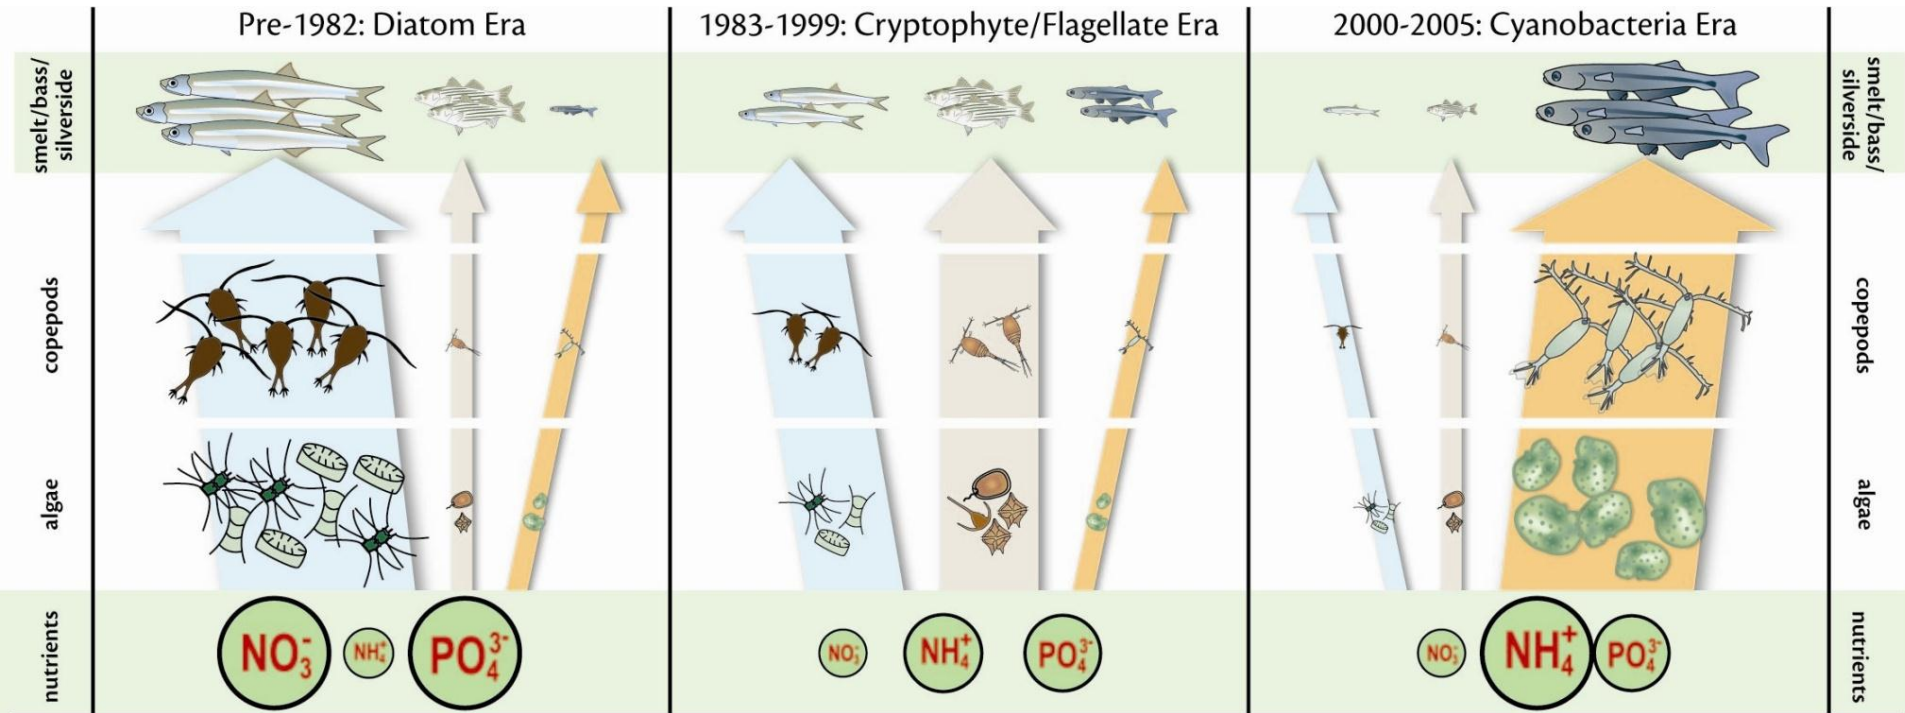

### 3) Flow set to proportion of volume, inputs are as surface area integrated values, simulates fully mixed bay with phytoplankton productivity restricted by irradiance

Sharp boundaries in biomass (the contours) at critical flow and NH<sub>4</sub> interactions

# Nutrient stoichiometric model

With increasing  $\text{NH}_4$  and decrease in  $\text{PO}_4$ , the phytoplankton and food webs have changed

## Nutrients

- $\text{NO}_3^-$  nitrate
- $\text{PO}_4^{3-}$  phosphate
- $\text{NH}_4^+$  ammonium

## Algae

- diatoms
- cryptophytes/flagellates
- cyanobacteria

## Copepods

- Eurytemora*
- Pseudodiaptomus*
- Limnithona*

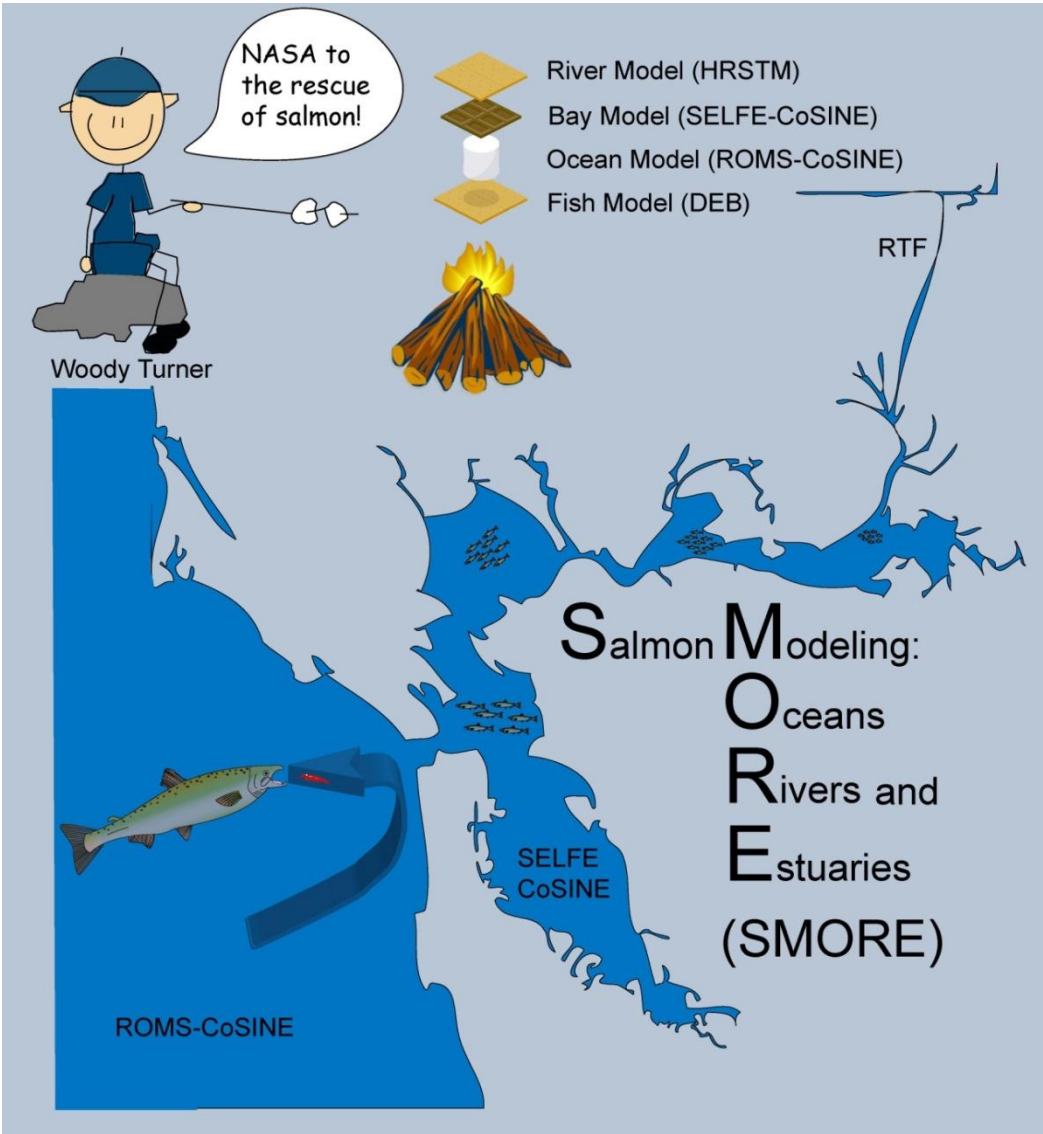

## Smelt/Silverside/Bass

- Delta/longfin smelt
- Young of Year striped bass
- silverside

Increasing contribution by  $\text{NH}_4$

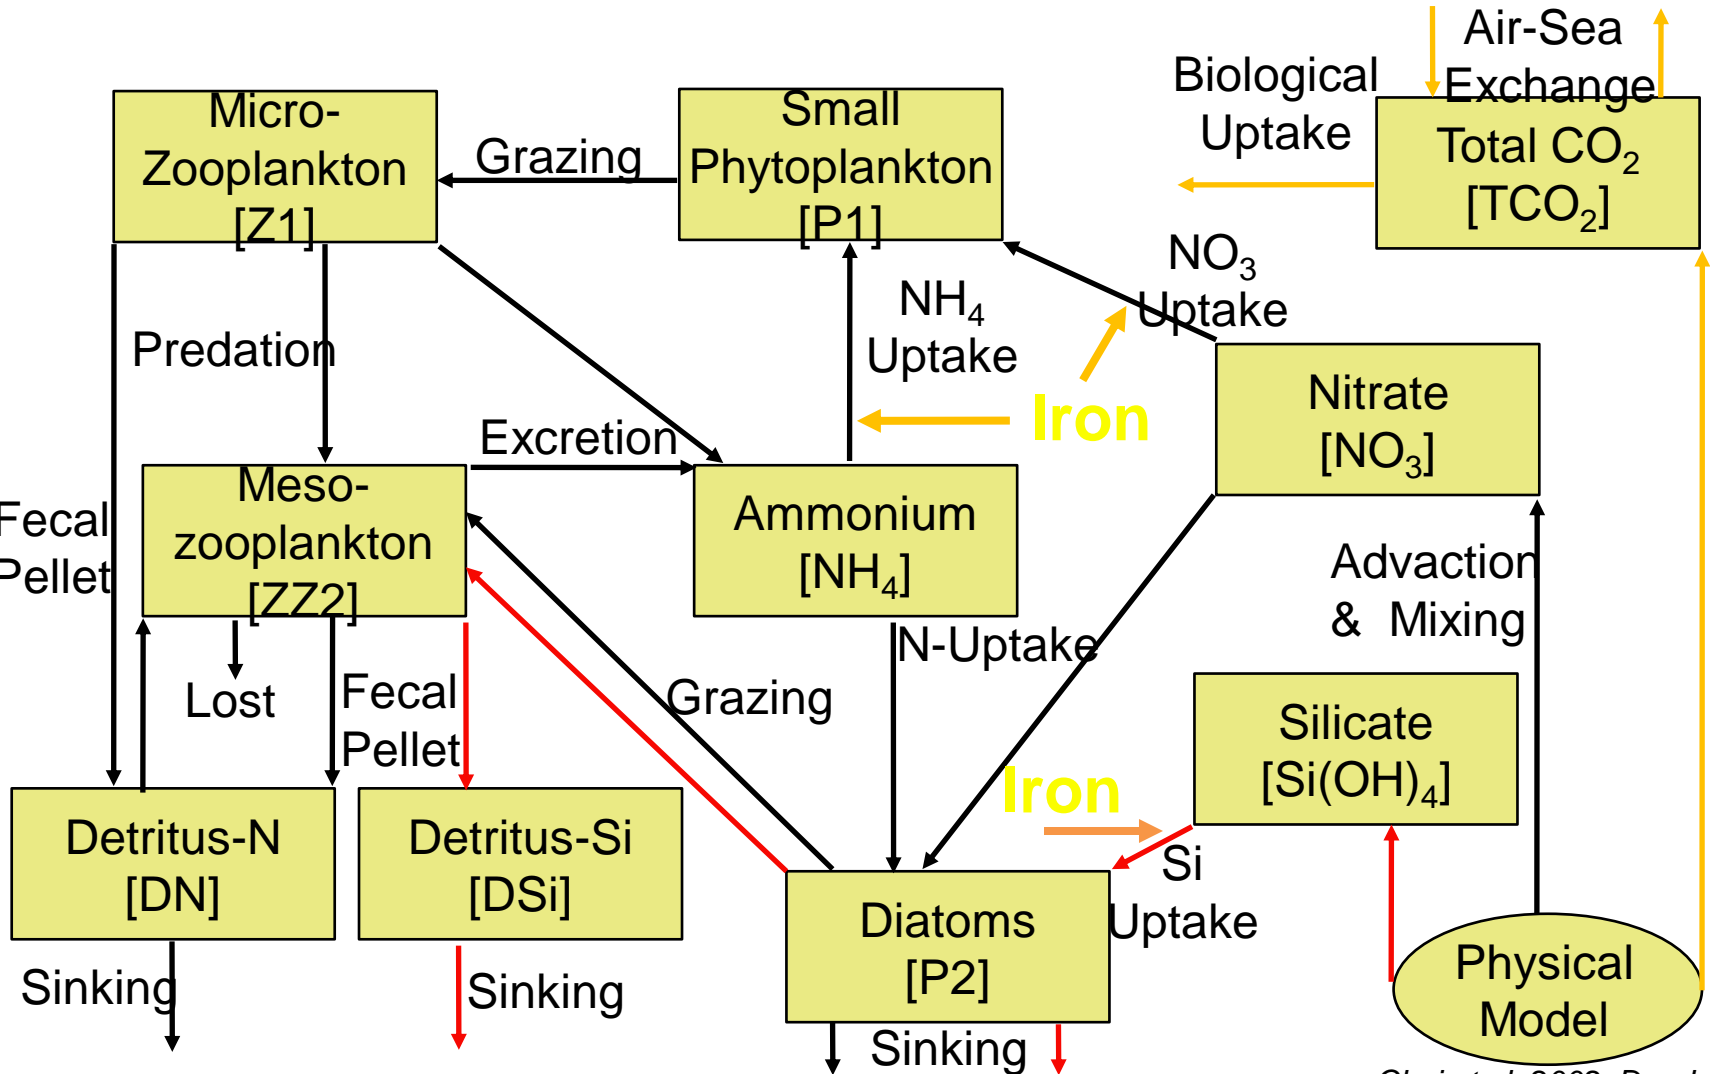

Glibert, 2010

# SMORE salmon model: new project to combine a lot of models to simulate salmon success from egg to adult

The lower trophic model to be used will be CoSiNE which will need to be modified for the estuary and rivers

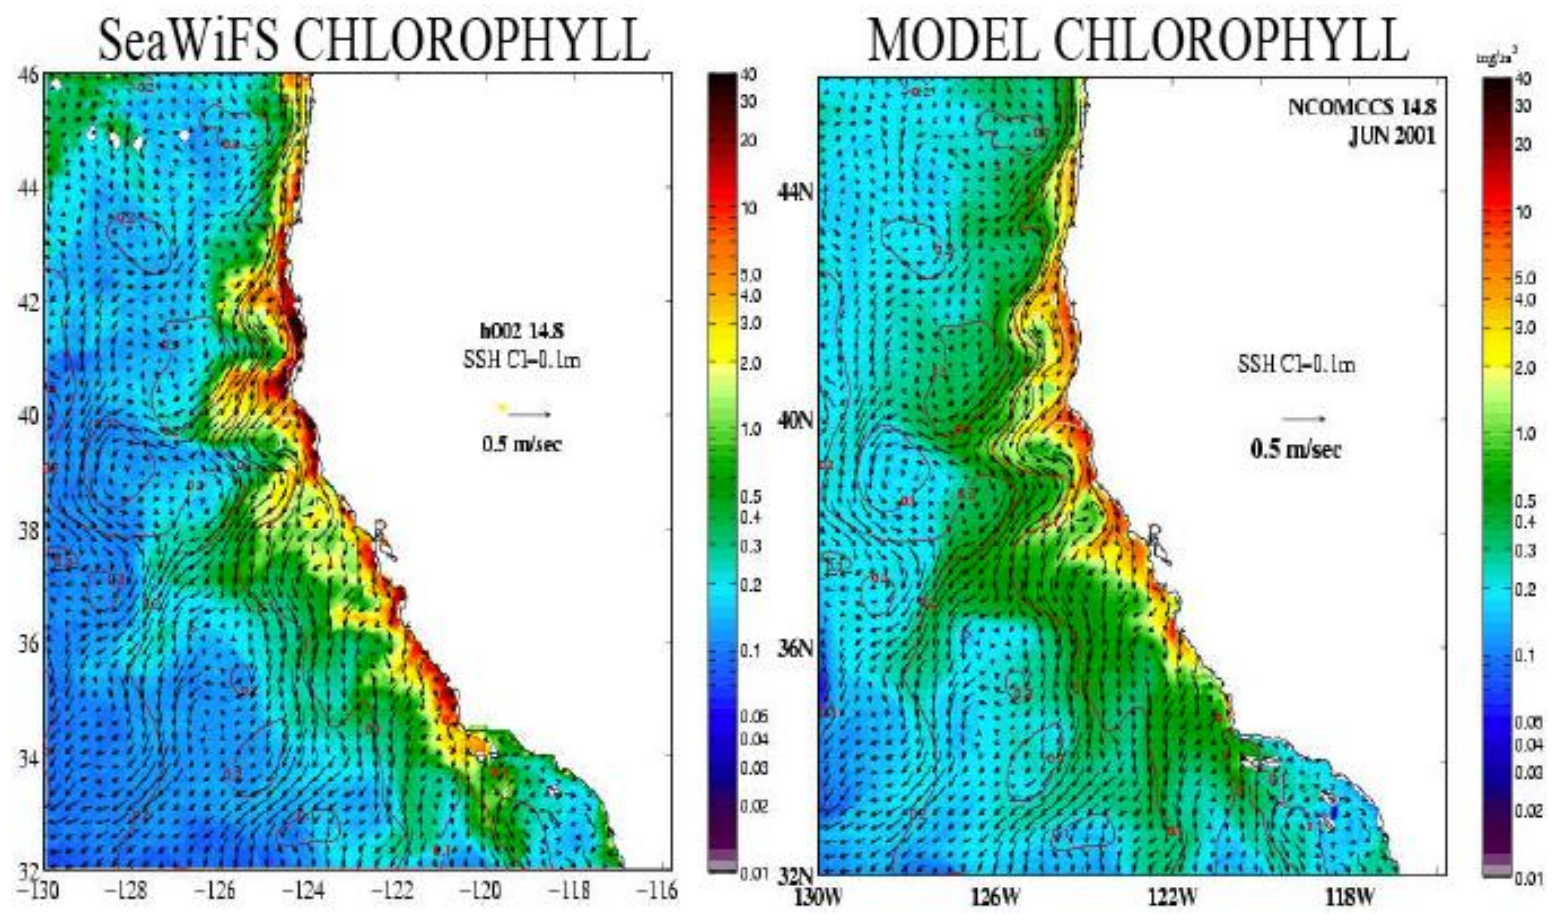

**Carbon, Silicate, Nitrogen Ecosystem Model CoSiNE,**

Chai et al. 2002; Dugdale et al. 2002
